

Software Engineering Project Write-up

For my project, I want to build a website that pulls data from Amazon and displays prices, sales (by day, month, and year), and trends for these metrics. I will do this by using Amazon APIs to track the data and basic web app technology. I would build the web app in JavaScript and use a database management system like MySQL. I want to do this project because at the current time, technology prices have skyrocketed with the age of AI. With my project, not only could I track Amazon sales, but I could also expand it to track sales from other companies that sell technology (like Walmart or Target) and tech-focused companies (like Newegg or Microcenter). This project relates to me because I built my first computer around early 2025, and RAM prices had not yet started to trend upward. This was because demand for AI data centers did not grow significantly until December 2025. The prices of tech have only gone up since then, and people getting into technology or building computers might want to find good deals on decent parts. Furthermore, people who already work in the computer technology field might also want to take advantage of these good deals. This web app can help users search for these deals more easily and spend less time searching Amazon to find specific items and exactly what they want. On this webapp, I want not only price and sale data, but also item descriptions, items it's compared to, and possibly benchmark data to accompany it. As another background feature, I would add some sort of pc builder, so when people look at parts and are looking to build a computer, they can see a "sample build" which takes parts that would work together and give decent performance, identified by certain tasks that the user would want their computer for. It is similar to the PCPartPicker website, but its main focus is to help users find good deals on online stores, primarily Amazon, as well as other websites such as Target and Walmart.
